Primary Care management of Overactive Bladder (OAB)

- Non-pharmacological treatments remain the mainstay for patients with OAB. All patients should have conservative treatment prior to commencement of medication or referral to secondary care.

- All medicines for OAB have similar dose-related efficacy. More than one agent (up to three in succession) may need to be tried, due to different side effect profiles – trial of at least 28 days is suggested (NICE CG171, 2013/ NICE NG123, 2019)

- Before commencing OAB drug treatment discuss:
  - The likelihood of success and associated common adverse effects and
  - The frequency and route of administration and
  - That some adverse effects such as dry mouth and constipation may indicate that treatment is starting to have an effect and that the patient may not see the full benefit until they have been taking the treatment for 4 weeks.
  - The long-term effects of anticholinergic medicines on cognitive function are uncertain

- Take into consideration the ‘Anticholinergic burden’ patient may have due to other medications. This is to reduce Central Nervous System & Gastro-intestinal side effects.

- In order people being treated for OAB every effort should be made to employ non-pharmacological treatment first. Use antimuscarinic drugs with caution in elderly patients who are at risk of, or have cognitive dysfunction.

- NICE recommends the most cost-effective agent is used- solifenacin 5mg once daily titrating up to 10mg daily after 4-6 weeks. Review patient for side effects.

If the first medicine is not effective or tolerated, offer alternative first line oxybutynin immediate release (IR). Initial dose is up to 5mg twice daily (start elderly at 2.5mg twice daily). Patients should be reviewed for side-effects. Do not offer oxybutynin immediate release to frail older patients who may be at higher risk of a sudden deterioration in their physical or mental health (NICE NG123).

- When similar dosage forms of OAB drugs are compared (IR to IR; SR to SR), the side effect profiles are similar. The IR formulations are generally associated with more anti-cholinergic side effects than the SR formulations which can affect compliance but are usually more expensive. See cost table.

- If patient has unmanageable side-effects or there is lack of efficacy with first/ second line agents, consider alternative medication taking into account possible advantages of specific agents and cost. e.g., trospium in elderly patients for its reduced CNS side effects.

- Currently there is very limited evidence for the use of mirabegron in combination with an antimuscarinic. More evidence would be required to assess whether combination is appropriate. However, this may be an option after specialist recommendation.

- Patients not responding to medical treatment (refractory OAB) should be referred to urology/urogynaecology department for further investigations and management.
Primary Care Management of Overactive Bladder

At the initial clinical assessment, categorise the urinary incontinence as **stress urinary incontinence (SUI)**, **urgency urinary incontinence (UUI)/overactive bladder (OAB)**, or mixed UI. Start initial treatment on this basis.

- OAB is urgency with or without urge incontinence, usually with frequency and nocturia
- UUI is involuntary leakage of urine associated with urgency
- Mixed urinary incontinence is involuntary leakage of urine associated with both urgency and physical stress (exertion, sneezing or coughing).

**Initial assessment**
- Full history
- Frequency/volume chart
- Consider measurement of post-void residue
- Urinalysis (to exclude infection in patients under 65 years old, haematuria and glycosuria)
- If suspected UTI in over 65- Obtain MSU and send to microbiology
- Physical examination
- Pad test if quantification of leakage is desired

**Conservative management – non-pharmacological treatments remain the mainstay for patients with OAB**

- All patients should have conservative treatment prior to commencement of medication or referral to secondary care.
- Patients can be referred to Continence Advisory Service for assessment and conservative treatment (see p5 for contact details)
- Should include patient education, lifestyle advice, bladder training and pelvic floor exercises

**Post-menopausal women:**
Intravaginal oestrogens are recommended for women with vaginal atrophy/OAB symptoms e.g. Ovestin 0.1% cream or Vagirux

**Lifestyle advice**
- Modify high or low fluid intake
- Advise on drugs, co-morbidity
- Avoid caffeine
- Smoking cessation, weight loss, exercise
- Constipation advice, healthy eating
- Consider intervention related to cognitive impairment (scheduled voiding)
- Offer timed or prompted voiding in elderly/care dependant people
- Offer pads or other containment device if needed

**Offer men**
- Temporary containment products
- Supervised bladder training

**Pelvic floor exercise (for women)**
Taught using vaginal or rectal examination (at least 3 months)

**Bladder retraining**
Minimum of 6 weeks (NICE 2006)

*Review at 3 months*  
Improved  
*Continue*
Before starting OAB drugs

When offering antimuscarinic drugs to treat OAB always take account of
- Coexisting conditions (e.g. poor bladder emptying, cognitive impairment or dementia, BPH, constipation, glaucoma)
- Anticholinergic burden- use of other existing medications affecting the total antimuscarinic load (see relevant resources on anticholinergic drugs/burden)
- Risk of adverse effects, including cognitive impairment

Discuss with the patient:
- The likelihood of success and associated common adverse effects and
- The frequency and route of administration and
- That some adverse effects such as dry mouth and constipation may indicate that treatment is starting to have an effect and that they may not see the full benefits until they have been taking the treatment for 4 weeks.
- The long-term effects of anticholinergic medicines on cognitive function are uncertain

Prescribe the lowest recommended dose when starting a new OAB drug to reduce the likelihood of side-effects

Reviewing medicine

Offer a review in primary care who remain on long-term medicine for overactive bladder or urinary incontinence every 12 months, or every 6 months if they are aged over 75. During the review, re-assess symptoms and quality of life and assess for adverse effects and the need to continue treatment.

Prescribing in elderly people/ people diagnosed with dementia

Antimuscarinic drugs may affect cognitive function in elderly people and those with dementia, hence when prescribing this group of drugs in elderly patients the following should be taken into account:

- In older people being treated for urinary incontinence, every effort should be made to employ non-pharmacological treatments first.
- Use antimuscarinic drugs with caution in elderly patients who are at risk of, or have, cognitive dysfunction.
- In older people who are being prescribed antimuscarinic drugs for control of urinary incontinence, consider the anticholinergic burden including other existing medications. Modifications to medications to help reduce CNS or GI adverse effects may be considered.
- Check mental function in patients on antimuscarinic medication if they are at risk of cognitive dysfunction.

Modified release oxybutynin and tolterodine are classified GREY-only use in those who may be at higher risk of a sudden deterioration in their physical or mental health (those with multiple comorbidities, functional impairments such as walking or dressing difficulties and any degree of cognitive impairment)
Pharmacological treatment of overactive bladder

**First line medication:** Solifenacin 5mg OD titrating to 10mg OD
(28d treatment cost £1.81)

- Review at 4 weeks
- Improved
- No benefit

**Alternative first line medication:** Oxybutynin immediate release
Oxybutynin 2.5mg or 5mg BD (28d treatment £1.59-1.74)
Titrate oxybutynin up to 5mg TDS as tolerated

- Review at 4-6 weeks
- Improved
- No benefit

**Both drugs should be trialled before moving to alternative agents**
The impact of adverse effects can be reduced by using a small starting dose and titrating dose slowly. Also consider using a modified release preparation for reducing troublesome side effects.

- Troublesome side-effects/ lack of efficacy
- Improved
- Review annually or every 6 months if >75yrs of age

**Change to alternative medication:**
This list is not in order of suggested use and choice of third line agent should take into account possible advantages of specific agents and cost. Clinicians should manage constipation and dry mouth before abandoning effective anti-muscarinic treatment. Management may include bowel management, fluid management, dose modification or alternative anti-muscarinic.

**Drug Tariff** – June 2023 and MIMS online

Both drugs should be trialled before moving to alternative agents

NICE concluded lack of evidence to show a difference in clinical effectiveness between OAB drugs and also a lack of evidence showing long term efficacy and thereby suggesting restricting the number of OAB drugs tried before seeking alternative recommended treatments (including referral to secondary care)

- Troublesome side-effects/ lack of efficacy
- Review at 4-8 weeks
- Improved

Consider referral to urology/ urogynaecology

- Review annually or every 6 months if >75yrs of age
Prescribing note - Mirabegron - GREY

NICE TA290 (June 2013) - mirabegron is an option only for patients in whom antimuscarinic drugs are ineffective, contra-indicated, or not tolerated. Follow treatment flowchart below.

MHRA, Oct 2015 has issued a safety warning stating mirabegron is contraindicated in patients with severe uncontrolled hypertension (systolic blood pressure ≥180 mm Hg or diastolic blood pressure ≥110 mm Hg, or both). Blood pressure should be measured before starting treatment and monitored regularly during treatment, especially in patients with hypertension.

Licensed doses of antimuscarinic drugs

Antimuscarinic adverse effects can limit treatment success. Adverse effects can be reduced by starting at a low dose and gradually increasing until a satisfactory clinical response is achieved.
